Living with the flood hazard

The Hutt River Floodplain Management Plan provides a high level of protection but remember floods can happen at any time of the year, night or day. The general Flooding Hazard fact sheet provides a lot of useful information on how to be prepared for flooding, but here are some further guidelines:

- Find out about the flood hazard at your home and other places your family use such as work and school
- In the Hutt Valley, the Upper Hutt and Hutt City Councils have the primary responsibility for passing flood warnings to the community and you should contact them if you are concerned about flood risk
- Learn about river flows at the Taita Gorge via the flow phone (this may be very busy if there is a flood alert).

Flood from streams

Never under-estimate the little guys! Events in 1976 and 2004 showed that small streams in the Hutt Valley can cause major flooding to areas nearby:

- December 1976, the Korokoro Stream flooded during a storm event and caused flooding in the Petone area, particularly at the Cornish Street/Hutt Road intersection. During this event in the Hutt Valley the Stokes Valley, Pine Haven and Waiketuki Streams also flooded.
- February 2004, heavy rain caused the Waiketuki Stream to burst its banks and caused major flooding to Riverside Drive, the Hutt Park raceway and the industrial area in Gracefield.

Hutt River floods

The Hutt River has a history of flooding. The first European/Pakeha settlers in the Wellington Region settled around Petone and Lower Hutt in the 1840s. By 1855, after experiencing floods (and earthquakes), many moved to Wellington. A major flood in 1898 covered the entire valley floor. This led to the construction of the first major stopbanks to protect Hutt residents. Some of the original stopbanks are still there today.

The Hutt River is a vigorous river and, although kept on its present course by stopbanks, it can still flood. Around 70,000 people live on the floodplain, and assets worth $6 billion are at risk. A big flood could cause considerable damage to businesses, services and homes in the Hutt Valley. Floods in 1998 and 2004 reminded us that the hazard is still there - you need to be prepared!

Current river information

- Heavy rain at the top of the catchment can result in extra water flowing down these watercourses and causing a large flood in the Hutt River.

- Learn about river flows at the Taita Gorge via the flow phone (this may be very busy if there is a flood alert).
- December 1976, the Korokoro Stream flooded during a storm event and caused flooding in the Petone area, particularly at the Cornish Street/Hutt Road intersection. During this event in the Hutt Valley the Stokes Valley, Pine Haven and Waiketuki Streams also flooded.
- February 2004, heavy rain caused the Waiketuki Stream to burst its banks and caused major flooding to Riverside Drive, the Hutt Park raceway and the industrial area in Gracefield.

Flooding Hazard – Hutt Valley

This fact sheet is about the flooding hazard in the Hutt Valley. It gives some advice on how to live with this hazard. Flooding Hazard – Hutt Valley is part of a series of fact sheets on natural hazards in the Wellington Region.

For more general information about floods and flooding, take a look at the Flooding Hazard fact sheet. In it you'll find answers to why floods happen, how floods are measured and how you can prepare yourself and your family.

The Hutt River catchment

There’s more to the Hutt River than you may think. The river is part of a much bigger system – its catchment. A catchment is an area of land which drains into a river system. Hutt River’s catchment contains all the rivers, streams and tributaries that flow down from the Tararua and Rimutaka mountain ranges, and from the Eastern and Western Hutt hills. All these watercourses eventually combine to become the Hutt River itself. This means that a storm or heavy rainfall in almost any part of the catchment could result in extra water flowing down these watercourses and causing a large flood in the Hutt River.

Hutt River Facts

- The catchment area is 655 km² – that’s more than seven times the area of the Wellington Harbour
- Starting in the Tararua Ranges and ending where the Hutt River enters Wellington Harbour, the main channel is 54km long
- Heavy rain at the top of the catchment can turn into floodwaters at the Hutt River mouth in less than seven hours.

How is the flooding hazard managed in the Hutt Valley?

Because the Hutt River floodplain has been so extensively developed, this stretch of the river needs to have effective and reliable flood protection works to shield the area’s people, assets and activities. The flood protection works cannot stop the river flooding, but they can try to keep the floodwater between the stopbanks, stopping the floodwaters from reaching the houses and businesses in the Hutt Valley.

How do we know there might be a flood?

We monitor rainfall in the catchment, together with river flow and levels. These are ways of alerting us to a possible flood risk. There are six rainfall and five river recording stations spread around the Hutt River catchment.

The Taita Gorge river level recording station is the key to monitoring flows from the catchment upstream. It is located at a point in the river downstream from where all the major streams of the catchment join the Hutt River.

Some of the larger flood events, their volume and estimated return periods are shown below.

Measuring floods

The amount of water flowing in a river is measured by a unit called a cumec. Cumec stands for cubic metres of water that flow past a given point in a second.

The frequency of a flood is measured by how often a flood of a particular size is likely to happen. So a 1 in 5, 1 in 50 or 1 in 100 year flood, for example, means that floods of certain sizes are statistically likely to happen once every 5, 50 or 100 years. Another way of saying how frequently a flood might happen is to talk about a return period.

In the case of the Hutt River, we are planning for a very big flood of 2300 cumecs. Such a flood has a return period of about 440 years - it is statistically a 1 in 440 year flood. That may sound as though a very big flood is only going to happen once in 440 years. But in reality two big floods can happen soon after each other. The return periods are reviewed every ten years.

The Hutt River Floodplain Management Plan

To plan for the flooding hazard in the Hutt Valley, the Hutt River Floodplain Management Plan was developed by Greater Wellington, Upper Hutt and Hutt City councils. The communities in the Hutt Valley played a big part in the process. Collectively it was decided that the level of flood protection preferred is one that will cope with a 2300 cumec flood. The Plan proposes a range of ways to protect the Hutt Valley communities against floods:

- Physical and Structural works: such as stopbanks, protecting and strengthening the sides of the river with rock and plantings (willows and natives).
- Other measures: such as providing information to the public and schools, having a flood warning system and having a family plan (Flood protection improvements and major flood events)

It is important to remember that this graph is only an indication of the varying level of protection provided to the community through flood protection improvements on the Hutt River. To find out more, get a copy of the Hutt River Floodplain Management Plan from the Greater Wellington website www.gw.govt.nz.

Even though all of the protection works will be fully upgraded and completed by 2040, there is already a high standard of flood protection in many places along the Hutt River. However, it is important to remember that flood protection systems are not a guarantee against flooding in all places. There will always be some areas that are still at risk.
